canaccessR: An open data product for analyzing transportation accessibility to employment and grocery stores in Canada's largest metropolitan areas.

João Pedro Figueira Amorim Parga, Anastasia Soukhov, Robert Nutifafa Arku, Christopher Higgins, Antonio Páez

Abstract

In this paper, we describe the {canaccesR} package, an open data product (ODPs) created using the R statistical language. {canaccess} is a data package that disseminates public transit travel time estimates (travel time matrices - TTM) to employment locations and grocery stores across the 12 largest Canadian metropolitan areas. We calculate these estimates for each Dissemination Area (DA) within these regions for the years 2019 and 2023. To do so, we use the {r5r} R package, General Transit Feed Specification (GTFS), OpenStreetMap (OSM), DMTI's Enhanced Points of Interest, and Statistics Canada Census data. This data package can be used by researchers, practitioners, and transit agencies to estimate accessibility to essential services across these regions. These estimates can be used to compare different regions across Canada in terms of their accessibility and to conduct within-region equity assessments regarding access to services, which can inform improvements in transportation policies related to accessibility. The package is still in its initial phase and may undergo expansions in the future by adding TTM's for other destinations (e.g., schools, healthcare facilities). Finally, as an ODPs, the {canaccess} package allows for open exploration, use, and contribution by users through its GitHub repository.

Keywords
Accessibility; public transit; open data products (ODPs); travel time; employment; grocery stores.

Introduction

The objective of this paper is to describe the {canaccesR} open data package. Its main contents are a set of public transit travel time matrices (TTM) estimates to employment and groceries stores from the 12 largest Canadian metropolitan areas in 2019 and 2023. These estimates were created by leveraging expertise in data science, computer programming, and transportation accessibility using the {r5r} R package (Pereira et al., 2021b). We used public transit schedule, transport network, population, and business location data from different sources to estimate these TTM's datasets.

Estimating accessibility - the potential offered by the transportation system to reach destinations (Páez et al., 2012) - requires specialized datasets and technical expertise. Recent efforts following an open-source and transparent philosophy have been made to disseminate useful data and information on transportation in the Canadian context (Soukhov and Páez, 2023). However, despite these initiatives, pre-processed and available data on transportation accessibility is scarse. Within this context, we expect to help filling this gap by the processing raw data into user-ready data and making them publicly available to advance knowledge on the field.

To create the package, we integrated and processed raw data from diverse sources, estimated TTM's for two destinations types (*e.g.*, jobs and groceries) across the largest cities in the country, and distributed these findings through this transparent and open source data product. Our main contribution is to provide analysis-ready data for Canada's largest cities on the topic of transportation accessibility, thus making urban analytics in the country more accessible and contributing to future research.

The package's main audiences are Canadian researchers in urban planning and transportation and transportation system agencies. We anticipate three primary uses for the open data product (ODP) described in this paper. First, the datasets allow for static assessment of the level of public transit accessibility across the country's largest cities before and after the COVID-19 pandemic. In other words, {canaccesR} makes it easier for those interested in comparing cities regarding their level of public transit accessibility to essential destinations (such as employment centers and groceries stores) to do so. Second, the temporal and spatial characters of the datasets made available here allow researchers to evaluate accessibility changes through time and across space within the largest Canadian urban areas. Third, as is now common practice in transportation accessibility research, used as inputs, these estimates can substantiate broader investigations on transportation justice and equity (Higgins et al., 2021; Humberto, 2023; Pereira et al., 2021a). For example, the TTM estimates allow for

evaluating the evolution of public transit's accessibility by income or spatial distribution across all Dissemination Areas (DA's) of each of the 12 cities in the sample (Parga et al., 2024). In other words, the package's contents can be used from straightforward assessments of accessibility in Canadian urban areas to more theoretically and morally complex evaluations of justice in the country's urban transportation system.

Besides this introduction, we organize this paper as follows. The next section contains a description of the data sources we used to construct the data package. Then, we recount the data processing necessary to create the package. Next, we go through the main contents of the data package, i.e., the travel time matrices estimated through our analysis. We present some basic descriptive statistics of these datasets, and elucidate how one can use them in accessibility analysis. Finally, we conclude by explaining how we expect {canaccesR} to contribute to the urban analytics and science community.

Data and methods

Raw data sources

The locations included in the data package comprise the 12 largest (population-wise) Census metropolitan areas (CMA's) based on the 2021 Canadian Census (Government of Canada, 2021) [*]. These locations are Toronto, Montreal, Vancouver, Ottawa-Gatineau, Calgary, Edmonton, Quebec City, Winnipeg, Hamilton, Kitchener-Cambridge-Waterloo, London, and Halifax. We used four main data sources to construct the {canaccesR} data package: General Transit Feed Specification (GTFS), OpenStreetMap (OSM), DMTI's Enhanced Points of Interest, and Statistics Canada Census data.

We manually collected and processed the GTFS files from all transit agencies within the selected CMA's to use their information on the public transit schedule in 2019 and 2023. The OpenStreetMap data for the selected areas were collected through the {osmextract} package (Gilardi and Lovelace, 2025). We used OSM data from 2019 and 2023, which provided information on the areas' transit network in two points in time. We collected data from the 2016 Canadian Census using the {cancensus} R package (von Bergmann et al., 2022) and used its information on the spatial distribution of the population and the number of workplace locations (employment) across the CMA's (Government of Canada, 2016). Finally, we gathered and cleaned the 2023 DMTI's Enhanced Points of Interest dataset to obtain the location of the groceries stores within every urban area selected (Inc., 2015). We filtered the locations within the DMTI dataset using the grocery stores code from the North American Industry Classification System (NAICS) and the Standard Industrial Classification (SIC). {**THE CODE FOR THIS ESTIMATIONS AND THE TRAVEL TIME MATRICES IS ON**

[*]We included Oshawa, Ontario, as part of the Greater Toronto Area (GTA) because of the former's proximity to the latter. We also included Abbotsford-Mission, British Columbia, as part of the Vancouver metropolitan area because of the former's proximity to a transit station on the region's West Coast Express commuter rail line.

Methods: travel time matrices processing

Using the {r5r} R package, we estimated public transit travel times for two destination types, grocery stores and jobs. For each amenity type, we chose a likely travel time and day of the week. We set a 15 minutes time window and the maximum trip duration to 120 minutes. For groceries stores, we set the departure date to a weekend afternoon and the departure time to between 12:00 PM to 12:15 PM on April 20, 2019 and April 22, 2023. For employment, we ran the analysis on a typical weekday morning rush-hour commute, more specifically 8:00 to 8:15 AM departure on Tuesday, April 16, 2019 and Tuesday, April 18, 2023 [^3]. In both cases, we assumed that walking was the mode of travel from origin to transit stop and from transit stop to destination. We aggregated all the resulting travel time matrices at the Dissemination Area (DA) level, which comprise the fundamental unit of analysis in data package. [^3]: The one exception is Quebec City, where the routing for 2019 occurs on a Saturday and Tuesday in June (instead of April) due to the GTFS data unavailability.

{canaccessR}'s contents

The main contents of the {canaccessR} package are the travel time matrices estimates for all the 12 largest Canadian cities.

Other sets of data are also available at the {canaccessR} package besides the travel time matrices. These are the boundaries, socio-economic and demographic data (e.g., population, number of dwellings, number of individuals below the Low Income Measure, etc.) of the selected CMA's, disaggregated by DA. In addition, the package also contains aggregated population statistics (for the selected CMA's) and transit revenue and ridership data aggregated by regional and national scale.

Descriptive statistics

Below, we present some of the basic statistics from the travel time matrices contained in the {canaccessR} package.

How to use {canaccessR}

This section presents some potential applications of the data package.

Concluding remarks

In this paper, we describe the {canaccesR} data package, created using the {r5r} R package and transit schedule, street network, employment, and population data. The package's main contents refers to the ready-to-use travel time matrices for public transit to reach employment and groceries stores in Canada's 12 largest urban areas. We expect the contents of the package to be used in transportation accessibility evaluations

within and across those regions. Moreover, these datasets can be used in further equity assessments that evaluate the distribution of accessibility across space and between social groups. Furthermore, in the spirit of open data products (Arribas-Bel et al., 2021), the package can be expanded through collaboration with other researchers by, for example, including travel time matrices to other essential destinations within the DMTI's dataset (*e.g.*, schools, healthcare, etc.). In other words, we hope that by making these datasets publicly available, future analysis can contribute to making Canada's transportation system more just and fair, considering accessibility's as the main social good of transportation (Martens, 2016), and the inherent connection between public transit and the "right to the city" (Coggin and Pieterse, 2015).

Declaration of Conflicting Interests

The author(s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Funding

The author(s) disclosed receipt of the following financial support for the research, authorship, and/or publication of this article: This work was supported by the Social Sciences and Humanities Research Council of Canada (*More description about the funding source after the review process*).
